**Unconventional Fixed-Radix Number Systems**

- ◆ Number system commonly used in arithmetic units - binary system with two's complement representation of negative numbers
- ◆ Other number systems have proven to be useful for certain applications -
  - ◆ Negative radix number system
  - ◆ Signed-digit number system
  - ◆ Sign-logarithm number system
  - ◆ Residue number system

ECE666/Koren Part.2 .2

Copyright 2010 Koren

## Negative-Radix Number Systems

- ◆ The radix  $r$  of a fixed-radix system - usually a positive integer
- ◆  $r$  can be negative -  $r = -\beta$  ( $\beta$  - a positive integer)
- ◆ Digit set -  $x_i = 0, 1, \dots, \beta-1$
- ◆ Value of  $n$ -tuple  $(x_{n-1}, x_{n-2}, \dots, x_0)$  -

$$X = \sum_{i=0}^{n-1} x_i (-\beta)^i.$$

- ◆ The weight  $w_i$  is -

$$w_i = \begin{cases} \beta^i & \text{if } i \text{ is even} \\ -\beta^i & \text{if } i \text{ is odd.} \end{cases}$$

## Example - Negative-Decimal System

- ◆ Negative-radix number system with  $\beta=10$  - **nega-decimal system**
- ◆ **Three-digit** nega-decimal numbers -
  - \*  $192_{-10} = 100 - 90 + 2 = 12$  ;  $012_{-10} = -10 + 2 = -8$
  - \* Largest positive value -  $909_{-10} = 909_{10}$
  - \* Smallest value -  $090_{-10} = -90_{10}$
  - \* Asymmetric range -  $-90 \leq X \leq 909$
  - \* Approximately 10 times more positives than negatives
- ◆ This is always true for odd values of  $n$  - opposite for even  $n$
- ◆ **Example** - the range for  $n=4$  is  $-9090 \leq X \leq 909$

## Negative-Radix Number Systems - Properties

- ◆ No need for a separate sign digit
- ◆ No need for a special method to represent negative numbers
- ◆ Sign of number is determined by the first nonzero digit
- ◆ No distinction between positive and negative number representations - arithmetic operations are indifferent to the sign of the numbers
- ◆ Algorithms for the basic arithmetic operations in the negative-radix number system are slightly more complex than their counterparts for the conventional number systems

ECE666/Koren Part.2 .5

Copyright 2010 Koren

## Example - Negative-Binary System

- ◆ Negative-radix numbers of length  $n=4$ ,  $\beta=2$  - **nega-binary system**
- ◆ Range -  $-10_{10}=1010_{-2} \leq X \leq 0101_{-2}=+5_{10}$
- ◆ When adding nega-binary numbers - carry bits can be either positive or negative
- ◆ **Example:**

-8	+4	-2	+1	
0	0	1	0	-2
0	0	1	1	-1
1	1	0	1	-3
- ◆ Nega-binary - proposed for signal processing applications
- ◆ Algorithms exist for all arithmetic operations
- ◆ Did not gain popularity: Main reason - not better than the two's complement system

ECE666/Koren Part.2 .6

Copyright 2010 Koren

## Signed-Digit Number Systems

- ◆ So far - digit set  $\{0, \dots, r-1\}$
- ◆ In the signed-digit (SD) number system, digit set is  $\{\bar{r-1}, \bar{r-2}, \dots, \bar{1}, 0, 1, \dots, r-1\}$  ( $\bar{i} = -i$ )
- ◆ No separate sign digit
- ◆ **Example:**
  - \*  $r=10, n=2$  ; digits -  $\{\bar{9}, \bar{8}, \dots, \bar{1}, 0, 1, \dots, 8, 9\}$
  - \* Range -  $\bar{99} \leq X \leq 99$  - 199 numbers
  - \* 2 digits, 19 possibilities each - 361 representations - redundancy
  - \*  $0\bar{1} = \bar{19} = -1$  ;  $0\bar{2} = \bar{18} = -2$
  - \* Representation of 0 (or 10) is unique
  - \* Out of 361 representations,  $361 - 199 = 162$  are redundant - 81% redundancy
  - \* Each number in range has at most two representations

ECE666/Koren Part.2 .7

Copyright 2010 Koren

## Reducing Redundancy in Signed-Digit Number Systems

- ◆ Redundancy can be beneficial - but more bits needed
- ◆ Reducing redundancy - digit set restricted to

$$x_i \in \{\bar{a}, \overline{a-1}, \dots, \bar{1}, 0, 1, \dots, a\} \quad \text{with} \quad \left\lceil \frac{r-1}{2} \right\rceil \leq a \leq r-1$$

- \*  $\lceil x \rceil$  - smallest integer larger than or equal to  $x$

- ◆ To represent a number in a radix  $r$  system - at least  $r$  different digits are needed
- ◆  $\bar{a} \leq x_i \leq a$  -  $2a+1$  digits
- ◆  $2a+1 \geq r$  and  $\left\lceil \frac{r-1}{2} \right\rceil \leq a$

ECE666/Koren Part.2 .8

Copyright 2010 Koren

## Example - SD Number System

- ◆  $r=10$  - range of  $a$  is  $5 \leq a \leq 9$
- ◆ If  $a=6$ ,  $n=2$  - 133 numbers in range  $\bar{6}\bar{6} \leq X \leq 66$
- ◆ 13 values for each digit - total of  $13^2 = 169$  representations - 27% redundancy
- ◆ 1 has only one representation - 01 -  $1\bar{9}$  is not valid
- ◆ 4 has two representations - 04 and  $1\bar{6}$

## Eliminating Carry Propagation Chains

- ◆ Calculating  $(x_{n-1}, \dots, x_0) \pm (y_{n-1}, \dots, y_0) = (s_{n-1}, \dots, s_0)$
- ◆ Breaking the carry chains - an algorithm in which sum digit  $s_i$  depends only on the four operand digits  $x_i, y_i, x_{i-1}, y_{i-1}$
- ◆ Addition time independent of length of operands
- ◆ An algorithm that achieves this independence:
- ◆ **Step 1:** Compute interim sum  $u_i$  and carry digit  $c_i$
- ◆  $u_i = x_i + y_i - r c_i$   
 where
 
$$c_i = \begin{cases} 1 & \text{if } (x_i + y_i) \geq a \\ \bar{1} & \text{if } (x_i + y_i) \leq \bar{a} \\ 0 & \text{if } |x_i + y_i| < a \end{cases}$$
- ◆ **Step 2:** Calculate the final sum  $s_i = u_i + c_{i-1}$

### Example - $r=10, a=6$

◆  $x_i = \bar{6}, \dots, 0, 1, \dots, 6$

◆ **Step 1** -  $u_i = (x_i + y_i) - 10 c_i$

◆ **Example** -  $3645 + 1456$

$$\begin{array}{r} 3645 \\ + 1456 \\ \hline 5101 \end{array}$$

$$c_i = \begin{cases} 1 & \text{if } (x_i + y_i) \geq 6 \\ \bar{1} & \text{if } (x_i + y_i) \leq \bar{6} \\ 0 & \text{otherwise} \end{cases}$$

$$\begin{array}{r} 3645x \\ + 1456y \\ \hline 0111c \\ 40\bar{1}1u \\ \hline 5101s \end{array}$$

- ◆ In conventional decimal number system - carry propagates from least to most significant digit
- ◆ Here - no carry propagation chain
- ◆ Carry bits shifted to left to simplify execution of second step

### Converting Representations

◆ This addition algorithm can be used for converting a decimal number to **SD** form by considering each digit as the sum  $x_i + y_i$  above

◆ **Example** - converting decimal  $6849$  to **SD**

$$\begin{array}{r} x_i + y_i \quad 6849 \\ \hline c \quad 1101 \\ u \quad \bar{4}\bar{2}4\bar{1} \\ \hline s \quad 1\bar{3}\bar{2}5\bar{1} \end{array}$$

◆ Converting **SD** to decimal - subtracting digits with negative weight from digits with positive weight

◆ **Example** - converting  $1\bar{3}\bar{2}5\bar{1}$  to decimal

$$\begin{array}{r} 10050 \\ -03201 \\ \hline 6849 \end{array}$$

## Proof of the Two-Step Algorithm

- ◆ To guarantee no new carry -  $|s_i| \leq a$
- ◆ Since  $|c_{i-1}| \leq 1$ ,  $|u_i|$  must be  $\leq a-1$  for all  $x_i, y_i$
- ◆ **Example** - largest  $x_i + y_i$  is  $2a \Rightarrow c_i = 1, u_i = 2a - r$   
since  $a \leq r-1, u_i = 2a - r \leq a-1$
- ◆ **Example** - smallest  $x_i + y_i$  for which  $c_i = 1$  is  $a \Rightarrow$   
 $u_i = a - r < 0$  or  $|u_i| = r - a$ ; to get  $|u_i| \leq a-1, 2a \geq r+1$
- ◆ Selected digit set must satisfy  $\left\lceil \frac{r+1}{2} \right\rceil \leq a \leq r-1$
- ◆ **Exercise** - show that for all values of  $x_i + y_i$ ,  $|u_i| \leq a-1$  if  $a \geq \left\lceil \frac{r+1}{2} \right\rceil$
- ◆ **Example** - for SD decimal numbers,  $a \geq 6$  guarantees no new carries in previous algorithm

## Addition of Binary SD Numbers

- ◆ Only one possible digit set -  $\{1, 0, \bar{1}\}$  -  $a=1$
- ◆ Interim sum and carry in addition algorithm -

$$u_i = (x_i + y_i) - 2c_i \quad c_i = \begin{cases} 1 & \text{if } (x_i + y_i) \geq 1 \\ \bar{1} & \text{if } (x_i + y_i) \leq \bar{1} \\ 0 & \text{if } (x_i + y_i) = 0. \end{cases}$$

- ◆ Summary of rules -

$x_i y_i$	00	01	$0\bar{1}$	11	$\bar{1}\bar{1}$	$\bar{1}1$
$c_i$	0	1	$\bar{1}$	1	$\bar{1}$	0
$u_i$	0	$\bar{1}$	1	0	0	0

- ◆ Addition is commutative -  $10, \bar{1}0, \bar{1}1$  not included
- ◆ In the binary case -  $a \geq \left\lceil \frac{r+1}{2} \right\rceil = 2$  cannot be satisfied
- ◆ No guarantee that a new carry will not be generated in the second step of the algorithm

## Addition - Carry Generation

◆ If operands do not have  $\bar{1}$  - new carries not generated

◆ Example -

\* In conventional representation - a carry propagates from least to most significant position

$$\begin{array}{r}
 \phantom{+} \phantom{0} \phantom{0} \dots \phantom{0} \phantom{1} \\
 + \phantom{0} \phantom{0} \phantom{0} \dots \phantom{0} \phantom{1} \\
 \hline
 1 \phantom{1} \phantom{1} \phantom{1} \dots \phantom{1} \phantom{0} \\
 \phantom{1} \phantom{1} \phantom{1} \dots \phantom{1} \phantom{0} \\
 \hline
 1 \phantom{0} \phantom{0} \phantom{0} \dots \phantom{0} \phantom{0}
 \end{array}
 \begin{array}{l}
 \\
 \\
 c_i \\
 u_i \\
 s_i
 \end{array}$$

\* Here - no carry propagation chain exists

◆ If operands have  $\bar{1}$  - new carries may be generated

◆ Example -

\* If  $x_{i-1}y_{i-1} = 0\bar{1}$  -  $c_{i-1} = 1$   
 and if  $x_i y_i = 0\bar{1}$  -  $u_i = 1$   
 $s_i = u_i + c_{i-1} = 1 + 1$  -  
 a new carry is generated

$$\begin{array}{r}
 \phantom{+} \phantom{0} \phantom{\bar{1}} \phantom{1} \phantom{\bar{1}} \phantom{1} \phantom{1} \\
 + \phantom{1} \phantom{0} \phantom{0} \phantom{\bar{1}} \phantom{0} \phantom{1} \\
 \hline
 1 \phantom{\bar{1}} \phantom{1} \phantom{\bar{1}} \phantom{1} \phantom{1} \phantom{0} \\
 \phantom{\bar{1}} \phantom{1} \phantom{\bar{1}} \phantom{0} \phantom{\bar{1}} \phantom{0} \\
 \hline
 * \phantom{*} \phantom{*} \phantom{*} \phantom{1} \phantom{0} \phantom{0}
 \end{array}
 \begin{array}{l}
 \\
 \\
 c_i \\
 u_i \\
 s_i
 \end{array}$$

\* Stars indicate positions where new carries are generated and must be allowed to propagate

## Addition - Avoiding Carry Generation

◆  $c_{i-1} = u_i = 1$  when  $x_i y_i = 0\bar{1}$  and  $x_{i-1} y_{i-1} = 11$  or  $01$

◆ Selecting  $c_i = 0$  -  $u_i = \bar{1}$

◆ However, for  $x_{i-1} y_{i-1} = \bar{1}\bar{1} \Rightarrow c_{i-1} = \bar{1}$   
 and we must still select  $c_i = \bar{1}$ ,  $u_i = 1$

◆ Similarly, when  $x_i y_i = 01$  and  $x_{i-1} y_{i-1} = \bar{1}\bar{1}$  or  $0\bar{1}$ ,  
 instead of  $u_i = \bar{1} \Rightarrow$  select  $c_i = 0$  &  $u_i = 1$

◆  $u_i$  and  $c_i$  can be determined by examining the two bits to the right  $x_{i-1} y_{i-1}$

◆  $u_i$  and  $c_i$  can still be calculated in parallel for all bit positions

$x_i y_i$	00	01	$0\bar{1}$	11	$\bar{1}\bar{1}$	$\bar{1}1$
$c_i$	0	1	$\bar{1}$	1	$\bar{1}$	0
$u_i$	0	$\bar{1}$	1	0	0	0

## Addition of Binary SD Numbers - Modified Rules

$x_i y_i$	00	01	0 $\bar{1}$	0 $\bar{1}$	11	1 $\bar{1}$
$x_{i-1} y_{i-1}$	-	neither is $\bar{1}$	at least one is $\bar{1}$	neither is $\bar{1}$	at least one is $\bar{1}$	-
$c_i$	0	1	0	0	1	1
$u_i$	0	$\bar{1}$	1	$\bar{1}$	1	0

◆ **Example** -  $1\bar{1}0\bar{1}17$

$$\begin{array}{r}
 \phantom{0}1\bar{1}0\bar{1}17 \\
 \underline{\phantom{0}0\bar{1}100-4} \\
 0\bar{1}001c \\
 \underline{\phantom{0}101\bar{1}\bar{1}u} \\
 0010\bar{1}3
 \end{array}$$

- ◆ Direct summation of the two operands results in  $001\bar{1}1$ , equivalent to  $0010\bar{1}$ , all representing  $3_{10}$

## Minimal Representations of Binary SD Numbers

- ◆ Representation with a minimal number of nonzero digits
- ◆ Important for fast multiplication and division algorithms
- ◆ Nonzero digits - add/subtract operations, zero digits - shift-only operations
- ◆ **Example** - Representations of  $X=7$ :
- ◆  $100\bar{1}$  is the minimal representation
- ◆ The **canonical recoding algorithm** generates minimal SD representations of given binary numbers

$$\begin{array}{r}
 \phantom{0}8 \phantom{0}4 \phantom{0}2 \phantom{0}1 \\
 \hline
 0 \phantom{0}1 \phantom{0}1 \phantom{0}1 \\
 1 \phantom{0}\bar{1} \phantom{0}1 \phantom{0}1 \\
 1 \phantom{0}0 \phantom{0}\bar{1} \phantom{0}1 \\
 1 \phantom{0}0 \phantom{0}0 \phantom{0}\bar{1} \\
 1 \phantom{0}\bar{1} \phantom{0}\bar{1} \phantom{0}1 \phantom{0}1 \\
 \vdots
 \end{array}$$

## Encoding of SD Binary Numbers

- ◆  $4 \times 3 \times 2 = 24$  ways to encode 3 values of a binary signed bit  $x$  using 2 bits,  $x^h$  and  $x^l$  (high and low)

$x$	Encoding 1 $x^h \ x^l$	Encoding 2 $x^h \ x^l$
0	0 0	0 0
1	0 1	0 1
$\bar{1}$	1 0	1 1

- ◆ Only nine are distinct encodings under permutation and logical negation - two have been used in practice
- ◆ Encoding #2 - a two's complement representation of the signed digit  $x$
- ◆ Encoding #1 is sometimes preferable
  - \* Satisfies  $x = x^l - x^h$  - 11 has a valid value of 0
  - \* Simplifies conversion from SD to two's complement - subtracting  $x_{n-1}, x_{n-2}, \dots, x_0$  from  $x_{n-1}, x_{n-2}, \dots, x_0$  using two's complement arithmetic
  - \* This requires a complete binary adder
  - \* A simpler conversion algorithm exists

## Conversion Algorithm - Simpler Circuit

- \* Binary signed digits examined one at a time, right to left
- \* All occurrences of  $\bar{1}$  are removed and the negative sign is forwarded to the most significant bit, the only bit with a negative weight in the two's complement representation
- \* The rightmost  $\bar{1}$  is replaced by 1 and the negative sign is forwarded to the left, replacing 0's by 1's until a 1 is reached, which "consumes" the negative sign and is replaced by 0
- \* If a 1 is not reached - the 0 in the most significant position is turned into a 1, becoming the negative sign bit of the two's complement representation
- \* If a second  $\bar{1}$  is encountered before a 1 is, it is replaced by a 0 and the forwarding of the negative sign continues
- \* The negative sign is forwarded with the aid of a "borrow" bit which equals 1 as long as a  $\bar{1}$  is being forwarded, and equals 0 otherwise

## Conversion Algorithm Rules

◆  $y_i$  -  $i$ -th digit of the SD number

◆  $z_i$  -  $i$ -th bit of the two's complement representation

◆  $c_i$  - previous borrow

◆  $c_{i+1}$  - next borrow

◆ For the least significant digit we assume  $c_0=0$

◆  $y_i - c_i = z_i - 2c_{i+1}$

$y_i$	$c_i$	$z_i$	$c_{i+1}$
0	0	0	0
0	1	1	1
1	0	1	0
1	1	0	0
$\bar{1}$	0	1	1
$\bar{1}$	1	0	1

## Conversion Algorithm - Cont.

◆ **Example** -  $-10_{10}$  - converting SD to two's complement

$y_i$	0	$\bar{1}$	0	$\bar{1}$	0
$c_i$	1	1	1	1	0
$z_i$	1	0	1	1	0

◆ Range of representable numbers in SD method - almost double that of the two's complement method

◆  $n$ -digit SD number must be converted to an  $(n+1)$ -bit two's complement representation

$y_i$	0	1	0	1	0	$\bar{1}$
$c_i$	0	0	0	0	1	1
$z_i$	0	1	0	0	1	1

◆ Without the extra bit position - the number **19** would be converted to **-13**
